

The Grace Study is a clinical research study evaluating the effectiveness and safety of an investigational study medicine on treating the signs and symptoms associated with endogenous Cushing syndrome.

To learn about study participation, talk to your doctor and visit CushingResearch.com today.

About Clinical Research Studies

What is a clinical research study?

Clinical research studies, also called clinical trials, test new medicines and other treatments to ensure that they successfully improve people's health and are safe to use. Before any clinical research study can begin, a review board evaluates the medicine or treatment to be sure it is safe and ethical for patient use. Once the study is over, if the medicine or treatment is judged to be safe and effective, a government agency, like the Food and Drug Administration (FDA) in the United States, decides if the medicine or treatment can be prescribed to patients.

Before deciding to participate, you should make sure you understand the potential side effects, risks, and benefits of being in the study. The study doctor will explain these to you. If there is anything you do not understand, you are encouraged to ask the study doctor.

Can I leave the study if I change my mind?

Participation in any clinical research study is completely voluntary, and you may choose to leave the study at any time for any reason. If you would like to leave the study, you should discuss this with your study doctor, who will give you information about how to do this safely.

Where can I get more information about the study?

Ask your doctor for more information and visit CushingResearch.com.

Cushing Syndrome Can Make
You Feel as If You're Losing Yourself

grace
STUDY

It's Not You, It's Cushing Syndrome

When you have Cushing syndrome, you may not recognize yourself anymore. Your looks are changing. You're feeling different. You're no longer doing the activities you once loved. It's almost as if you're no longer you—all because of the distinct signs and symptoms of this condition.

Cushing syndrome, also referred to as hypercortisolism, is a condition that occurs when the body produces too much cortisol, a naturally occurring hormone in our bodies.

The release of extra cortisol is usually caused by the presence of noncancerous tumors in the body, and this is called endogenous Cushing syndrome. The Grace Study is specifically enrolling individuals with endogenous Cushing syndrome.

With Cushing syndrome, several signs and symptoms can appear, and they can be different in every patient. Some of the common signs and symptoms include:

- High blood sugar
- High blood pressure
- Weight gain
- Muscle weakness
- Acne
- Low bone mass
- Depression

The Grace Study is currently testing relacorilant, an investigational study medicine, for the treatment of these symptoms.

The Search for You

We are looking for adults ages 18 to 80 who have been diagnosed with endogenous Cushing syndrome to take part in the Grace Study.

Individuals will be evaluated to determine their eligibility to participate in the study. Those who qualify will receive the investigational study medicine, study-related medical exams, and laboratory tests at no cost. Qualifying participants may receive compensation for their participation.

Learn More about the Grace Study

We understand how difficult having Cushing syndrome can be. It can completely change your appearance and, more importantly, how you feel about yourself and your life. For more information about the Grace Study and what you can expect if you qualify for participation, visit CushingResearch.com.

We encourage you to talk to your doctor for more information. If you know someone else who has been diagnosed with endogenous Cushing syndrome, please pass this information along and direct them to the study website.
